

Phenology Cues in Tropical Dry Forests

Arturo Sanchez-Azofeifa, PhD, PEng
Cassidy Rankine, Gilberto Zonta-Pastorello
Centre for Earth Observation Sciences (CEOS)
Earth and Atmospheric Sciences Department
University of Alberta

Microsoft WSN Workshop
Sao Paulo, Brazil
November 2010

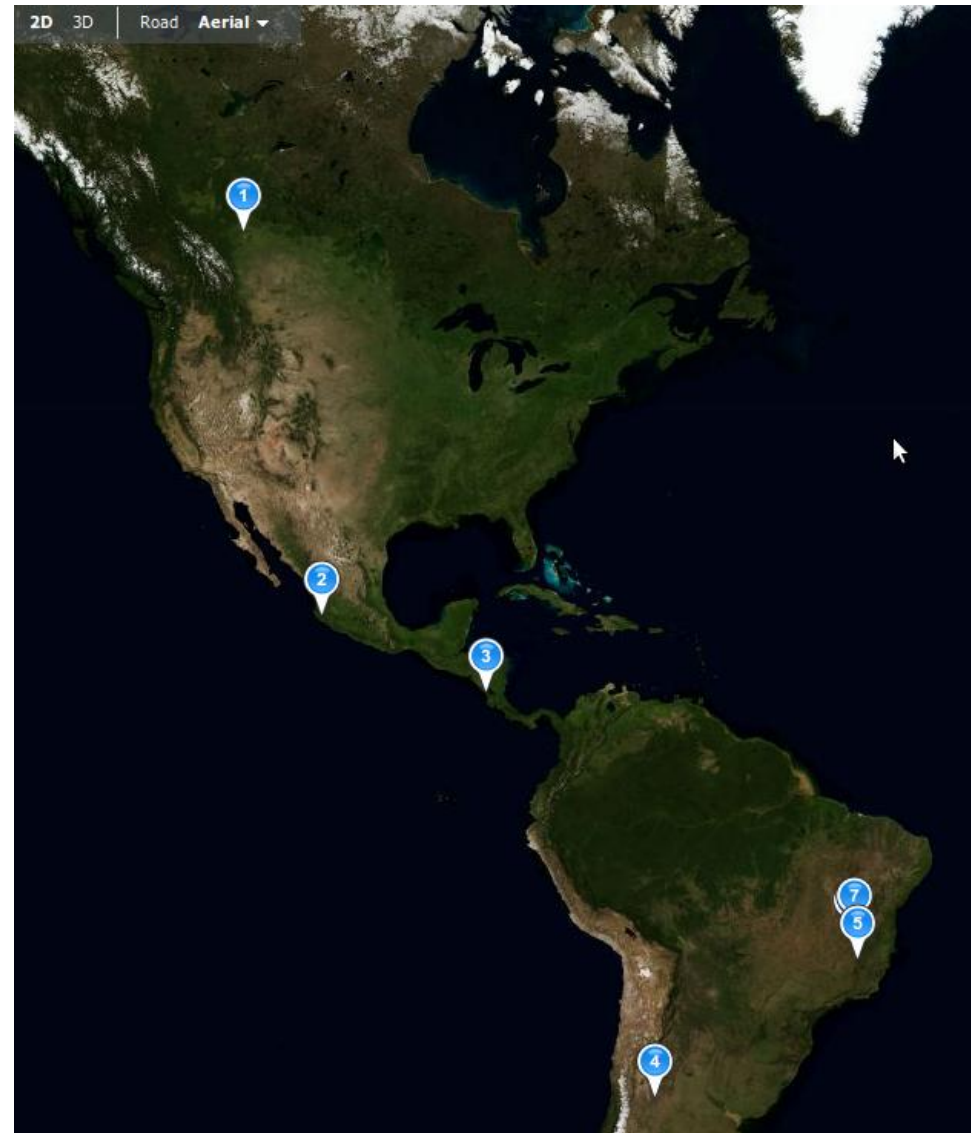

What do we know?

- Well... Very little to start with (although 47% of the tropics are tdfs).
- Dry forests lag on long term studies aimed to understand their response to climate change. In fact, dry forest lag on a ratio of 1:300 scientific papers when compared with tropical rainforests.
- Ecological studies in dry forestes are systematic in two regions: Chamela-Cuixmala biosphere reserve, Mexico; and Santa Rosa National Park; Costa Rica.
- Tropical Forests are not considered part of any global networks aimed to link climate change observations and models to phenological response; nor are part of long term monitoring efforts.
- Tropical dry forests present well define phenological signals allowing for unique opportunities to evaluate their response to climate change and specially drought effects.

Enviro-Net Project

- **Seven Sites**
 - Argentina, Brazil (3), Canada, Costa Rica, Mexico
- **36 Deployments**
 - 14 Wired Phenology Towers
 - logger & 4-8 sensors
 - 12 Wired Ground Deployments
 - logger & 3-8 sensors
 - 2 Wireless Phenology Towers
 - logger, node & 6 sensors
 - 8 Wireless Ground Deployments
 - logger, 5-10 node, 15-50 sensors

Wireless Optical Phenology Systems (WOPS®)

- 5-10m above canopy (5-20m total height)
- Physical Variables Measured:
 - Air/soil temperature
 - Air/soil humidity
 - Solar Radiation
 - Photosynthetically Active Radiation (PAR)
- Derived Variables:
 - Vegetation Indexes
 - APAR, fAPAR
 - Vapour Pressure Deficit
 - Carbon and water fluxes

Wireless Ground Deployments Nodes:

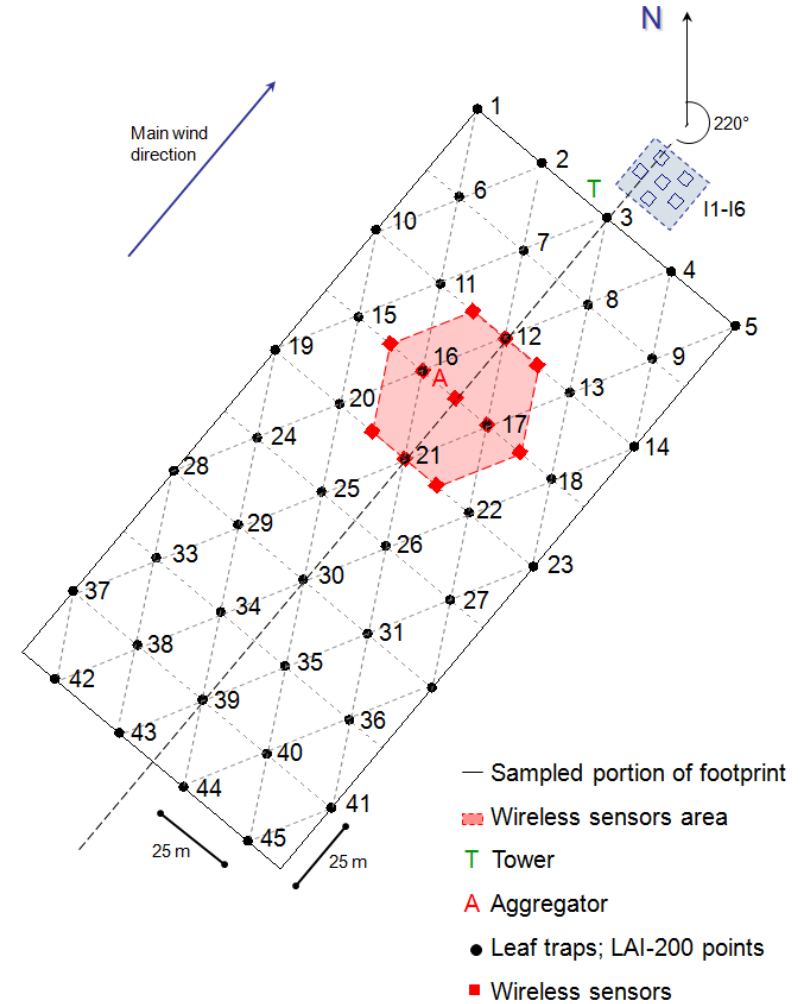

- Current deployments (2007-2010):
5 – 20 nodes per deployment
- Planned deployments (2011-2014): up to
100 nodes per deployment

Chamela, Mexico Sampling Design

Localization of litterfall traps, LAI-2000 measurement points and wireless PAR sensors within the flux tower footprint at the Chamela Biological Station.

Serra do Cipo, Minas Gerais, Brazil

- Soil temperature station
- WSN Collector: PAR, T/RH
- WSN Aggregator, Collector: PAR, T/RH
- Phenology tower

Mata Seca State Park, Minas Gerais, Brazil

-  Phenology tower
-  Wireless sensor network (PAR, T/RH)
-  Understory meteorological station (rain, T/RH, PAR, Soil Moisture)
-  Understory Wireless sensor network PAR experiment
-  Phenology digital camera & logger
-  Meteorological station

Visualize Data:

Use this page to view readings in real-time using simple graphs, maps, and tables to gain insight into every cluster.

Retrieve Data:

Export the data from any cluster into a comma separated value (csv) file for deeper analysis with tools such as GNUplot and Microsoft Excel.

Upload Data:

For clusters that do not have any internet connectivity, use this tool to upload data into the database.

- Data management within Wireless Sensor Networks (WSNs), e.g., algorithms for in-network query processing
- Exploiting the (potential) synergy between networking issues and data management within WSNs, e.g., logical topology and packet scheduling oriented by query semantics
- Indexing of spatio-temporal data and time-series with a focus on re-using sound and industrially tested technologies, e.g., B⁺-trees
- Data mining, web data and social network analysis

Conclusion

- WSN for environmental monitoring are providing important information on cues controlling phenological processes in tropical dry forests.
- Not all dry forests follow the common “soil moisture” model, other sites indicate less dependence on this variable.
- New data analysis and visualization tools are necessary to handle MASSIVE amounts of information specially on real time transmissions.
